# Creating Consistent Looking Web Sites

Asst. Prof. Dr. Özgü Can

### **Consistent Pages**

Make your web site as consistent as possible.

 Consistency gives your site a professional appearance and it helps your visitors to find their way around the site.

- With most web sites, only part of the page changes when you go from one page to another.
- The parts that don't change usually include common regions like the header, a menu, and the footer.
- To create web pages with a consistent layout, you need a way to define these relatively static regions in a single template file.

- You only need to modify the master page and the pages based on this master will pick up the changes automatically.
- Looks like a normal ASPX page
  - Not a true ASPX page
    - Can not be requested in the browser.
    - It only serves as the template that real web pages (content pages) are based on.

• <u>Instead of</u> the @ <u>Page</u> directive, a master page <u>uses</u> an @ <u>Master</u> directive that identifies the file as a master page:

```
<%@ Master Language="C#" %>
```

 Just like a normal ASPX page, a master page can have a Code Behind file, identified by its CodeFile and Inherits attributes:

```
<%@ Master Language="C#" AutoEventWireup="true"
CodeFile="Frontend.master.cs" Inherits="MasterPages_Frontend" %>
```

 To create regions that content pages can fill in, you need to define ContentPlaceHolder controls in your page like this:

```
<asp:ContentPlaceHolder id="ContentPlaceHolder1" runat="server">
</asp:ContentPlaceHolder>
```

You can create as many placeholders as you like.

#### **Content Pages**

- Normal ASPX files
- Connected to a master page using the MasterPageFile attribute of the Page directive:

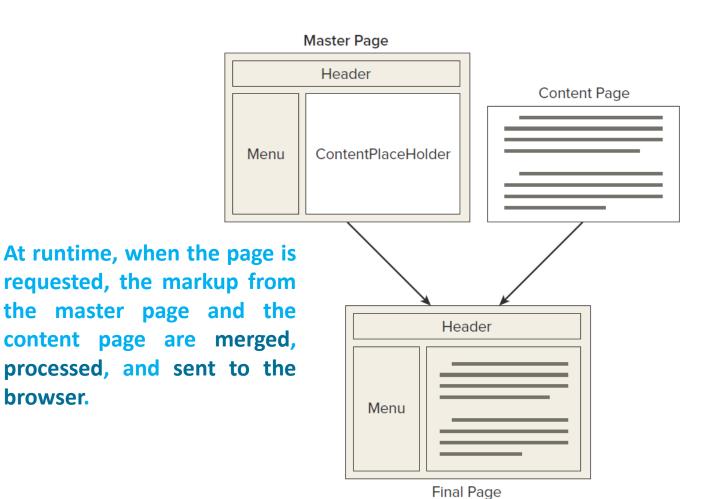

```
<%@ Page Title=" " Language="C#" MasterPageFile="~/MasterPages/Frontend.master"
AutoEventWireup="true" CodeFile="Default.aspx.cs" Inherits="_Default" %>
```

#### **Content Pages**

 The page-specific content is then <u>put inside</u> a Content control that points to the relevant ContentPlaceHolder:

Points to the ContentPlaceHolder that is defined in the master page.

#### Runtime

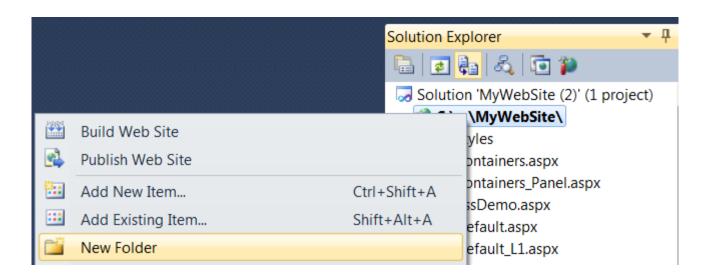

browser.

 It's often easier to store them in a separate folder.

 Just like normal ASPX pages, they support the Inline Code Model as well as the Code Behind Model.

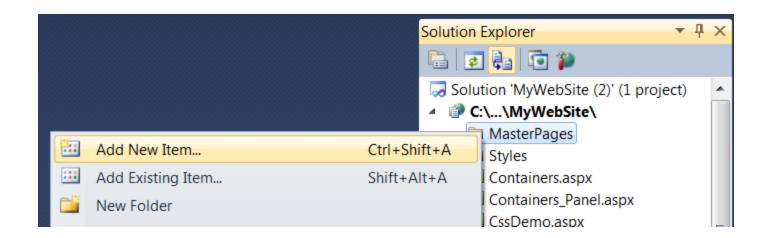

# **Example Master Page**

Add MasterPages folder

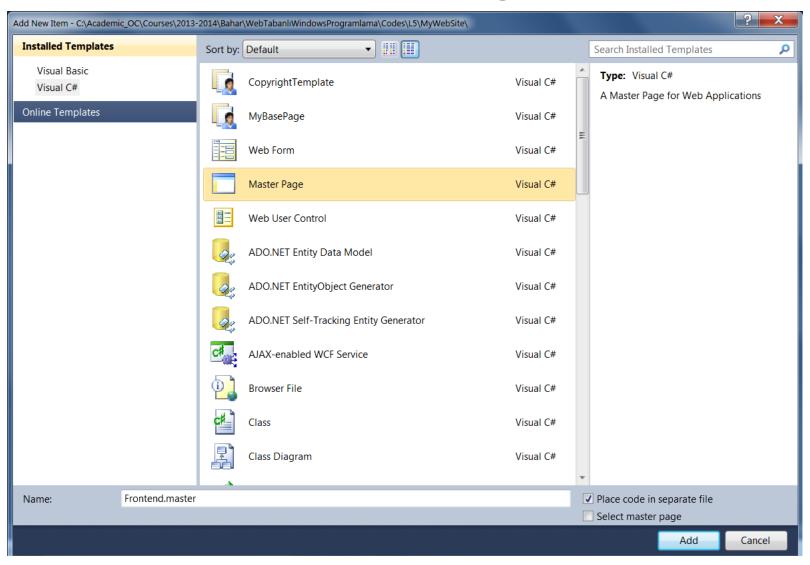

# Example Master Page

Add New Item to the MasterPages folder

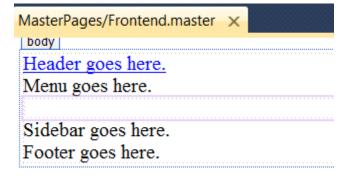

# **Example Master Page**

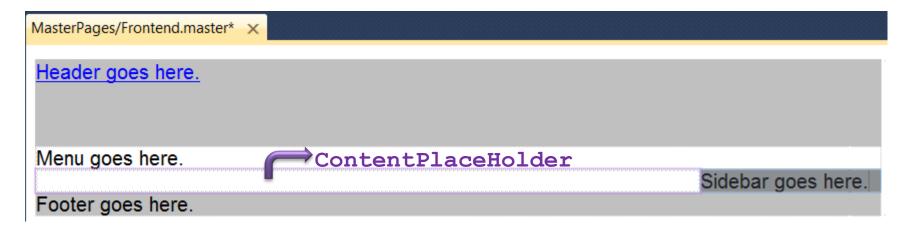

# Example Master Page

## **Example Master Page**

In Design View:

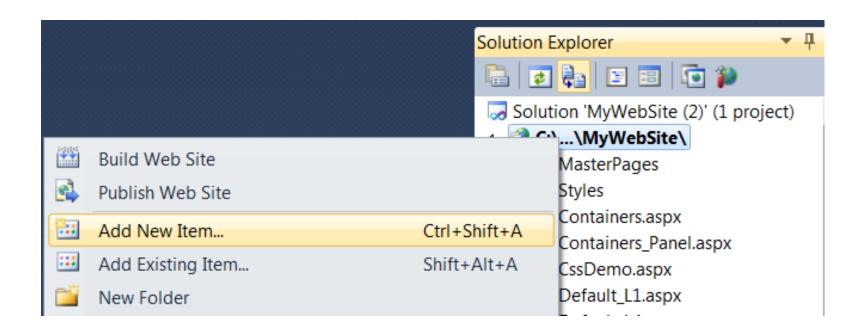

• Drag Styles.css from the Styles folder in the Solution Explorer onto the master page.

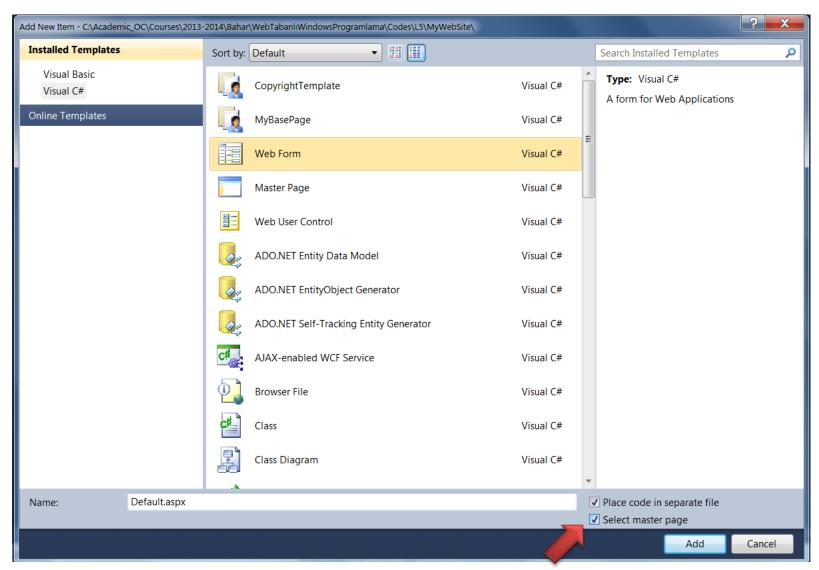

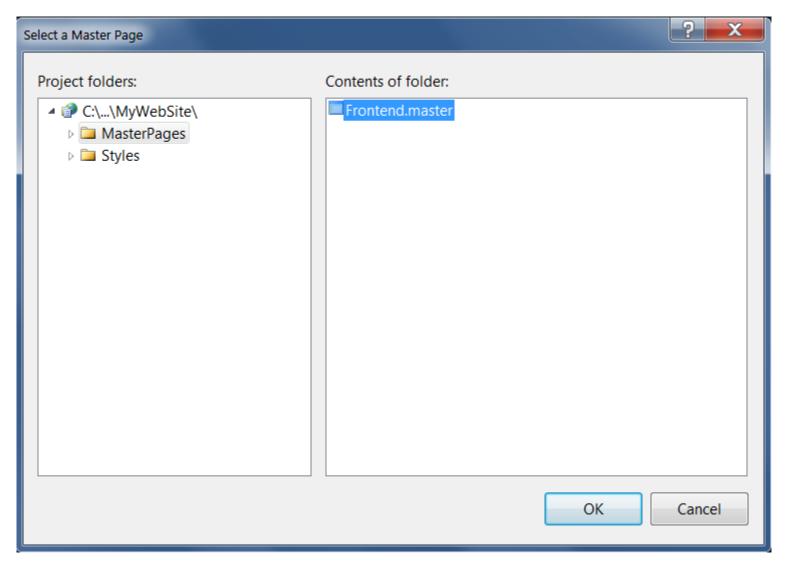

• In **Default.aspx** → Copy all the HTML between **MainContent** <div>> tags

• Delete/Rename Default.aspx

Add New Item

 Instead of getting a full page with HTML as you got with standard ASPX pages, you now only get two <asp:Content> placeholders

```
<asp:Content ID="Content1" ContentPlaceHolderID="head" Runat="Server">
</asp:Content>
<asp:Content ID="Content2" ContentPlaceHolderID="cpMainContent" Runat="Server">
</asp:Content>
```

 In Design View → Everything is grayed out and read-only, except for the <asp:Content> region for cpMainContent.

 Click once inside the cpMainContent placeholder and paste the old markup from the Default.aspx.

View Source

View in browser.

Header goes here.

Menu goes here.

Hi there visitor! Welcome to my Web Site :-)

Sidebar goes here.

I'm glad that you are visiting my web site <a href="http://www.mywebsite.com">http://www.mywebsite.com</a>

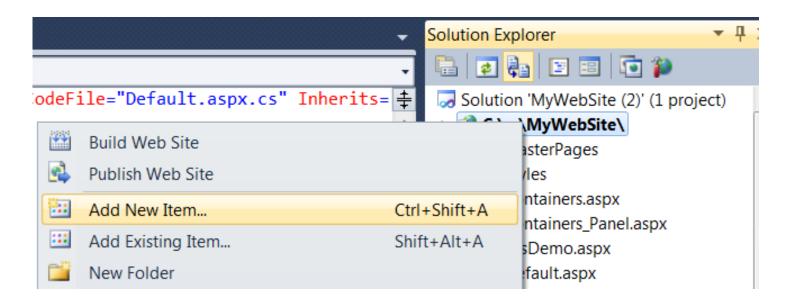

Feel free to have a look around.

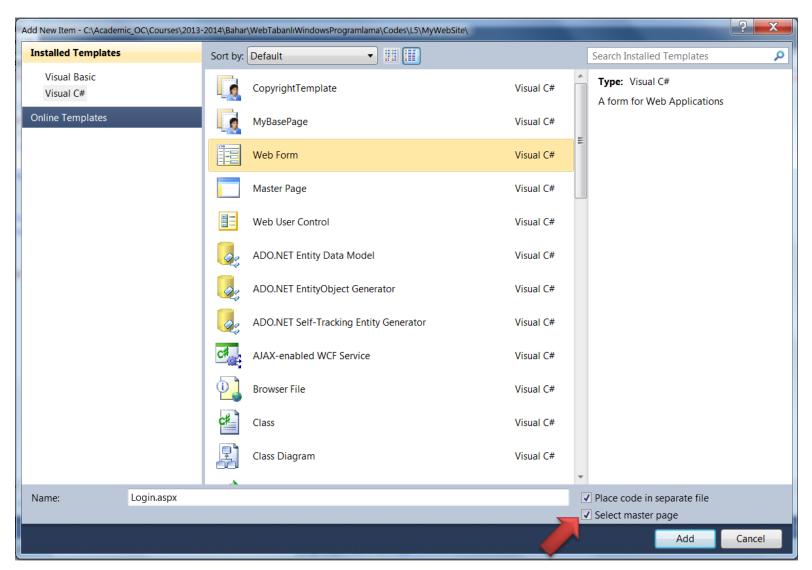

Footer goes here.

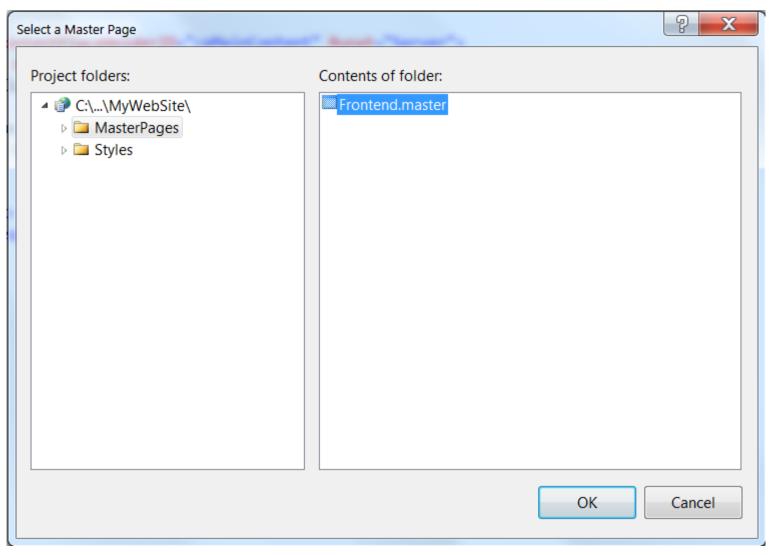

View source code in the browser.

```
<div id="PageWrapper">
   <div id="Header"><a href="./">Header goes here </a></div>
   <div id="MenuWrapper">Menu goes here</div>
   <div id="MainContent">
   <h1 style="padding: 0px; margin: 0px 0px 10px 0px">
       Hi there visitor! Welcome to my Web Site :-)
   </h1>
   I'm glad that you are visiting my web site <a href="http://www.mywebsite.com">
       http://www.mvwebsite.com</a>
   <strong>Feel</strong> <span class="style1"><strong>free</strong></span> to have a
       <a href="DefaultWcss2.aspx">look around</a>.
   </div>
   <div id="Sidebar">Sidebar goes here</div>
   <div id="Footer">Footer goes here</div>
</div>
```

- Switch back to Visual Studio
- Add New Item

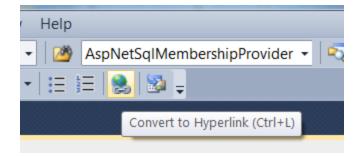

Create an <h1> element

- Go back to **Default.aspx**
- Create a new paragraph

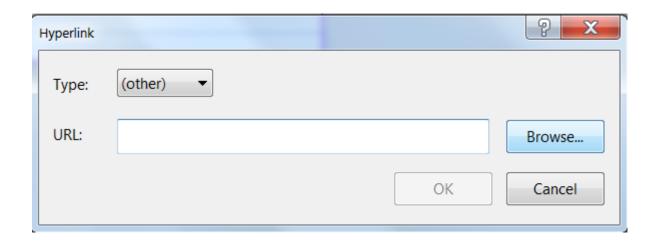

In Design View 
 Highlight log in

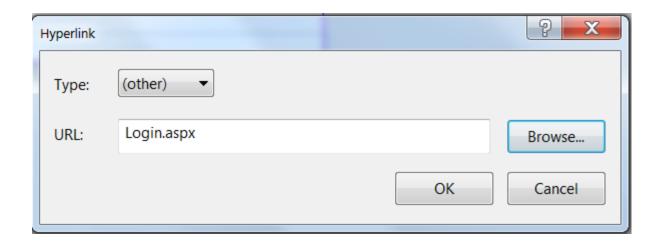

Convert to Hyperlink

#### • Click Browse

#### • Select Login.aspx

View in browser

You can log in here	
Footer goes here.	
<u>Header goes here.</u>	
Menu goes here.	
Log in to My Website	Sidebar goes here.

## **Nesting Master Pages**

- A nested master page is a master that is based on another master page.
- Content pages can then be based on the nested master page.
- This is useful if you have a web site that targets different areas that still need to share a common look and feel.
  - For example: A corporate web site that is separated by departments.

### **Master Page Caveats**

In a normal ASPX page:

```
<asp:Button ID="Button1" runat="server" Text="Click Me" />
```

• In the final HTML, ends up with:

```
<input type="submit" name="Button1" value="Click Me" id="Button1" />
```

However, inside an <asp:Content> control:

Auto generated ID of the master page

#### **Master Page Caveats**

- Because the name and id of the HTML elements are changed, they add considerably to the size of the page.
  - Gets worse with nested master pages:

```
<input type="submit" name="ct100$ct100$cpMainContent$ContentPlaceHolder1$Button1"
    value="Click Me" id="cpMainContent_ContentPlaceHolder1_Button1" />
```

 You should <u>keep the IDs</u> of your ContentPlaceHolder and Content controls as short as possible.

#### **Master Page Caveats**

 Master page <u>improves</u> the consistency and maintability of your site.

- Base Page → Another way to improve consistency
  - Centralize the behavior of the pages in your web site.

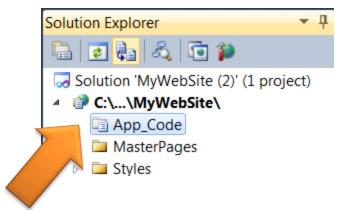

#### **Base Page**

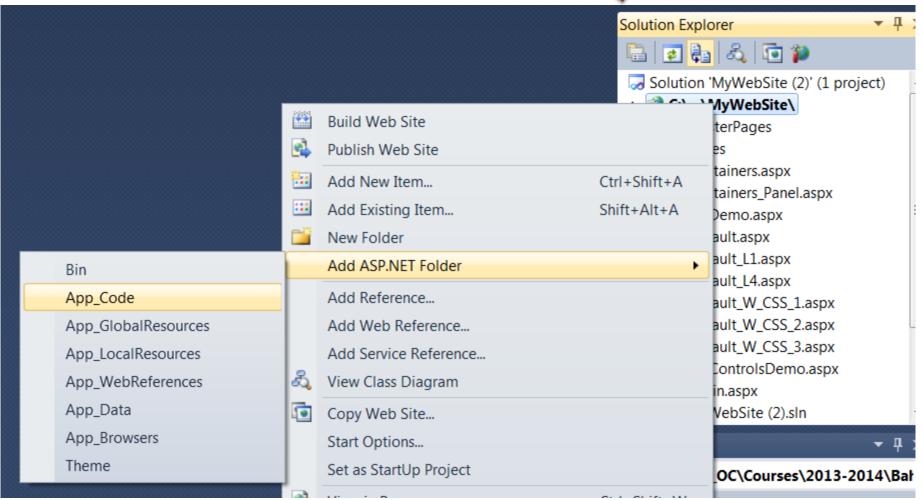

- By default, pages in your web site inherit from the Page class defined in the System. Web. UI namespace.
  - However, in some circumstances this behavior is not enough and you need to add your own stuff.
- You can easily insert your own base page class between a web page and the standard Page class.

#### **Base Page**

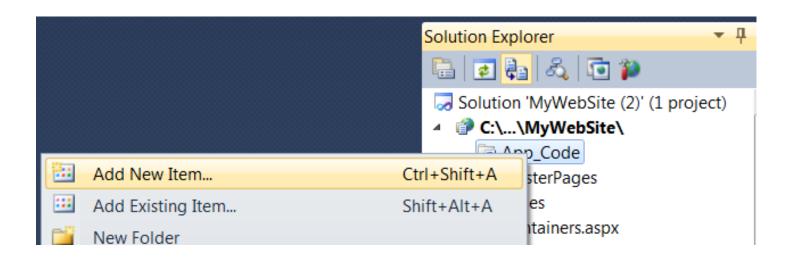

- To have your pages inherit from this base page, you need to do two things:
  - Create a class that inherits from System.Web.UI.Page in the App\_Code folder of your web site.
  - 2. Make the web pages in your site inherit from this base page instead of the standard Page class.

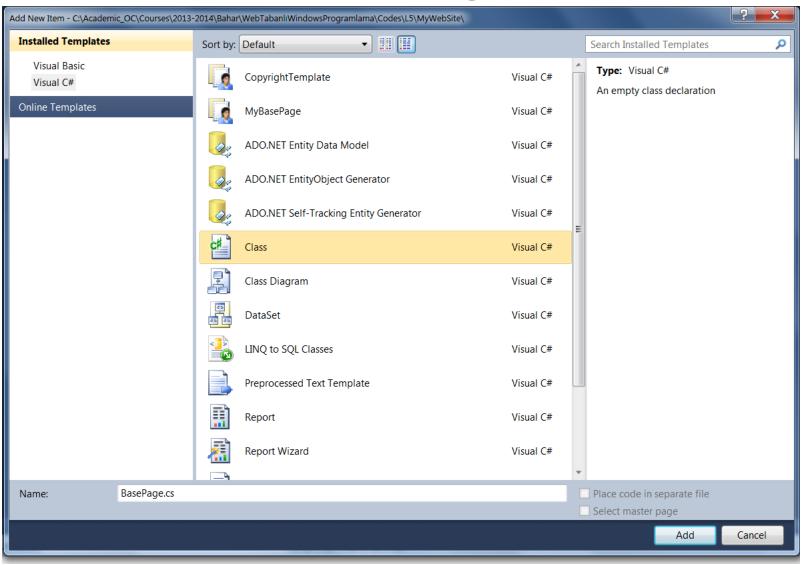

Add App\_Code folder

Add New Item to App\_Code folder

```
public class BasePage:System.Web.UI.Page
   private void Page_PreRender(object sender, EventArgs e)
        if (this.Title == "Untitled Page" || string.IsNullOrEmpty(this.Title))
            throw new Exception("Page title cannot be \"Untitled Page\" or an empty string.");
   public BasePage()
        // TODO: Add constructor logic here
        //
        this.PreRender += new EventHandler(Page_PreRender);
```

Open Code Behind file of Login.aspx

```
public partial class Login : System.Web.UI.Page
    protected void Page_Load(object sender, EventArgs e)
public partial class Login : BasePage
    protected void Page_Load(object sender, EventArgs e)
```

#### View Login.aspx in browser

Server Error in '/MyWebSite' Application.

Page title cannot be "Untitled Page" or an empty string.

Description: An unhandled exception occurred during the execution of the current web request. Please review the stack trace for more information about the error and where it originated in the code.

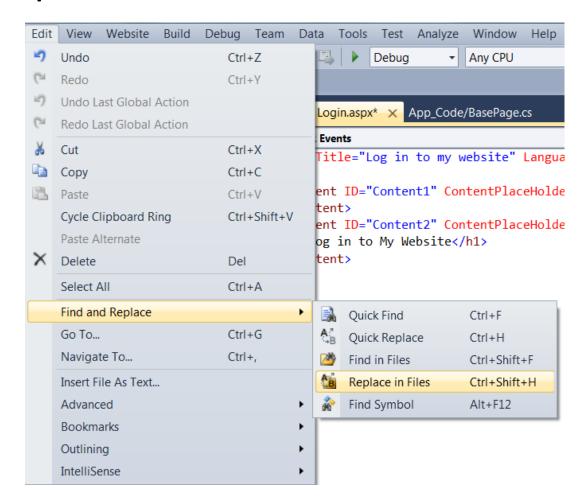

Exception Details: System.Exception: Page title cannot be "Untitled Page" or an empty string.

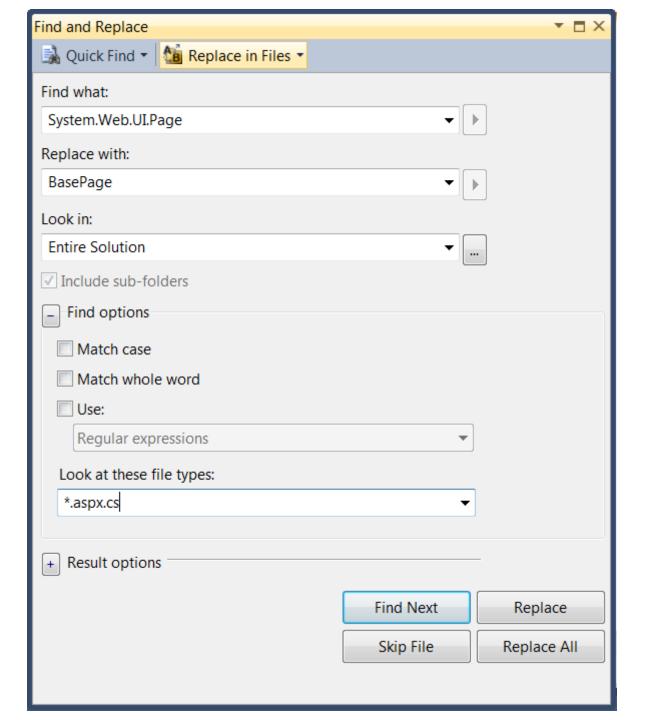

#### Source Error:

- Go back to Visual Studio
- Set value to **Title** attribute in the @**Pag**e directive

<%@ Page Title="Log in to my website" Language="C#" MasterPageFile="~/MasterPages/Frontend.master"</pre>

Make a replacement for the rest of the files

• View Login.aspx in browser

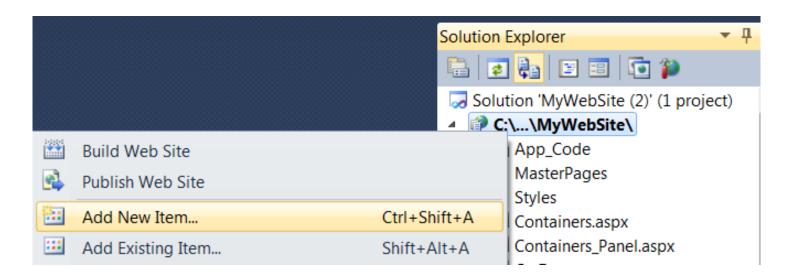

Menu goes here.

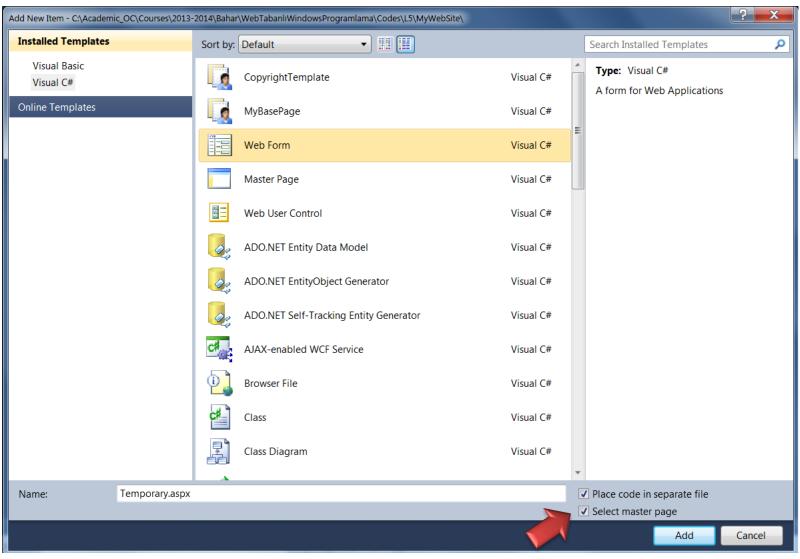

Log in to My Website

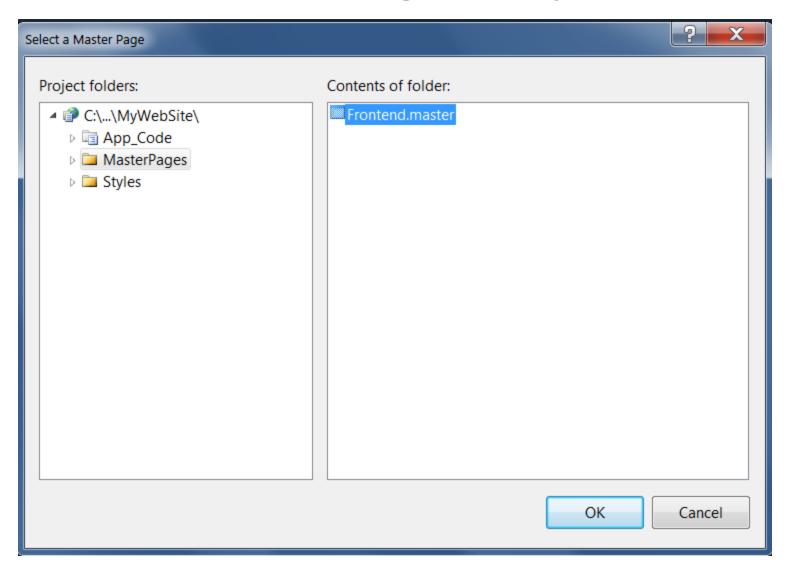

Sidebar goes here.

Footer goes here.

Add New Item

Open Code Behind file

```
public partial class Temporary : System.Web.UI.Page
   protected void Page_Load(object sender, EventArgs e)
}
                         Name of
                                       Name of
                        the folder
                                       the page
public partial class $relurlnamespace$ $safeitemname$ : BasePage
   protected void Page_Load(object sender, EventArgs e)
```

 In Source View → Change the Inherits attribute

Add a comment about copyright notice.

```
<%@ Page Title="" Language="C#" MasterPageFile="~/MasterPages/Frontend.master" Au
<%--Please email to me@mywebsite.com for copyright.--%>
<asp:Content ID="Content1" ContentPlaceHolderID="head" Runat="Server">
</asp:Content>
<asp:Content ID="Content2" ContentPlaceHolderID="cpMainContent" Runat="Server">
</asp:Content></asp:Content>
```

Save all changes

#### Export Template Wizard

#### **Choose Template Type**

This wizard will allow you to export a project or project item from the current solution to a template which future projects can then be based upon.

Which type of template would you like to create?

Project template

A project template will allow a user to create a new project based on your exported project. A user will be able to utilize your template from the New Project dialog box for client projects and from the New Website dialog box for websites.

Item template

An item template will allow a user to add your item to one of their existing project. Your template will be available to the user from the Add New Item dialog box.

From which project would you like to create a template?

MyWebSite

What language category should this template appear under in the New Project dialog box?

Visual C#

    <asp:Content ID="Content1" ContentPlaceHolderID="head" Runat="Server">
    </asp:Content>
    <asp:Content ID="Content2" ContentPlaceHolderID="cpMainContent" Runat="Server">
    </asp:Content>
           public partial class TestPage : BasePage
                 protected void Page Load(object sender, EventArgs e)
```

#### Page Life Cycle

How a page is served by a web server to the browser  $\rightarrow$  Life cycle of a page

- 1. Page Request
- 2. Start
- 3. Page Initialization
- 4. Load
- 5. Validation
- 6. Postback Event Handling
- 7. Rendering
- 8. Unload

#### Please READ

http://msdn.microsoft.com/en-us/library/ms178472(v=vs.100).aspx

PHASE	DESCRIPTION
Page request	A request to an ASPX page starts the life cycle of that page. When the web server is able and allowed to return a cached copy of the page, the entire life cycle is not executed. In all other situations, the page enters the start phase.
Start	In this phase, the page gets access to properties like Request and Response that are used to Interact with the page's environment. In addition, during this phase the PreInit event is raised to signal that the page is about to go into the Initialization phase.
Page initialization	During this phase, the controls you have set up in your page or added programmatically become available. Additionally, the Page class fires three events: Init, InitComplete, and PreLoad. Also during this phase, the control properties are loaded from View State and Control State again during a postback. So, for example, when you change the selected item in a DropDownList and then cause a postback, this is the moment where the correct item gets preselected in the drop-down list again, which you can then work with in your server-side code.
Load	During this phase the page raises the Load event.
Validation	In the validation phase, the Validation controls used to validate user input are processed.
Postback event handling	During this phase, the controls in your page may raise their own events. For example, the DropDownList may raise a SelectedIndexChanged event when the user has chosen a different option in the list. Similarly, a TextBox may raise the TextChanged event when the user has changed the text before she posted back to the server. When all event processing is done, the page raises the LoadComplete event. During this phase the PreRender event is raised to signal that the page is about to render to the browser. Shortly after that, SaveStateComplete is raised to indicate that the page is done storing all the relevant data for the controls in View State.
Rendering	Rendering is the phase where the controls (and the page Itself) output their HTML to the browser.
Unload	The unload phase is really a clean-up phase. This is the moment where the page and controls can release resources like database connections. During this phase, the Unload event is raised so you can handle any cleanup you may need to do.
